(54) Title: CHIMERIC FLAVIVIRUS VACCINES

(57) Abstract: A chimeric live, infectious, attenuated virus containing a yellow fever virus, in which the nucleotide sequence for a prM-E protein is either deleted, truncated, or mutated, so that functional prM-E protein is not expressed, and integrated into the genome of the yellow fever virus, a nucleotide sequence encoding a prM-E protein of a second, different flavivirus, so that the prM-E protein of the second flavivirus is expressed.

BEST AVAILABLE COPY

CHIMERIC FLAVIVIRUS VACCINES

5

Background of the Invention

This invention relates to infectious, attenuated viruses useful as vaccines against diseases caused by flaviviruses.

Several members of the flavivirus family pose current or potential threats to global public health. For example, Japanese encephalitis is a significant public health problem involving millions of at risk individuals in the Far East. Dengue virus, with an estimated annual incidence of 100 million cases of primary dengue fever and over 450,000 cases of dengue hemorrhagic fever worldwide, has emerged as the single most important arthropod-transmitted human disease.

15 Other flaviviruses continue to cause endemic diseases of variable nature and have the potential to emerge into new areas as a result of changes in climate, vector populations, and environmental disturbances caused by human activity. These flaviviruses include, for example, St. Louis encephalitis virus, which causes sporadic, but serious, acute disease in the midwest, southeast, and western United States; West Nile virus, which causes febrile illness, occasionally complicated by acute encephalitis, and is widely distributed throughout Africa, the Middle East, the former Soviet Union, and parts of Europe; Murray Valley encephalitis virus, which causes endemic nervous system disease in Australia; and
20 Tick-borne encephalitis virus, which is distributed throughout the former Soviet Union and eastern Europe, where its *Ixodes* tick vector is prevalent and responsible for a serious form of encephalitis in those regions.

25

Hepatitis C virus (HCV) is another member of the flavivirus family, with a genome organization and replication strategy that are similar, but

-3-

E protein from the irreversible conformational changes caused by maturation in the acidic vesicles of the exocytic pathway (Guirakhoo *et al.*, Virology 191:921-931, 1992).

The cleavage of prM to M protein occurs shortly before release of virions by a furin-like cellular protease (Stadler *et al.*, J. Virol. 71:8475-8481, 1997), which is necessary to activate hemagglutinating activity, fusogenic activity, and infectivity of virions. The M protein is cleaved from its precursor protein (prM) after the consensus sequence R-X-R/K-R (X is variable), and incorporated into the virus lipid envelope together with the E protein.

Cleavage sequences have been conserved not only within flaviviruses, but also within proteins of other, unrelated viruses, such as PE2 of murine coronaviruses, PE2 of alphaviruses, HA of influenza viruses, and p160 of retroviruses. Cleavage of the precursor protein is essential for virus infectivity, but not particle formation. It was shown that, in case of a TBE-dengue 4 chimera, a change in the prM cleavage site resulted in decreased neurovirulence of this chimera (Pletnev *et al.*, J. Virol. 67:4956-4963, 1993), consistent with the previous observation that efficient processing of the prM is necessary for full infectivity (Guirakhoo *et al.*, 1991, *supra*; Guirakhoo *et al.*, 1992, *supra*; Heinz *et al.*, Virology 198:109-117, 1994). Antibodies to prM protein can mediate protective immunity, apparently due to neutralization of released virions that contain some uncleaved prM. The proteolytic cleavage site of the PE2 of VEE (4 amino acids) was deleted by site-directed mutagenesis of the infectious clone (Smith *et al.*, ASTMH meeting, December 7-11, 1997). Deletion mutants replicated with high efficiency and PE2 proteins were incorporated into particles. This mutant was evaluated in lethal mouse and

-5-

Philadelphia, 1995). In addition, the yellow fever virus has been studied at the genetic level (Rice *et al.*, Science 229:726-733, 1985) and information correlating genotype and phenotype has been established (Marchevsky *et al.*, Am. J. Trop. Med. Hyg. 52:75-80, 1995). Specific examples of yellow fever substrains that can be used in the invention include, for example, YF 17DD (GenBank Accession No. U17066), YF 17D-213 (GenBank Accession No. U17067), YF 17D-204 France (X15067, X15062), and YF-17D-204, 234 US (Rice *et al.*, Science 229:726-733, 1985; Rice *et al.*, New Biologist 1:285-296, 1989; C 03700, K 02749). Yellow Fever virus strains are also described by Galler *et al.*, Vaccine 16 (9/10):1024-28, 1998.

Preferred flaviviruses for use as the second flavivirus in the chimeric viruses of the invention, and thus sources of immunizing antigen, include Japanese Encephalitis (JE, *e.g.*, JE SA14-14-2), Dengue (DEN, *e.g.*, any of Dengue types 1-4; for example, Dengue-2 strain PUO-218) (Gruenberg *et al.*, J. Gen. Virol. 67:1391-1398, 1988) (sequence appendix 1; nucleotide sequence of Dengue-2 insert; Pr-M: nucleotides 1-273; M: nucleotides 274-498; E: nucleotides 499-1983) (sequence appendix 1; amino acid sequence of Dengue-2 insert; Pr-M: amino acids 1-91; M: amino acids 92-166; E: amino acids 167-661), Murray Valley Encephalitis (MVE), St. Louis Encephalitis (SLE), West Nile (WN), Tick-borne Encephalitis (TBE) (*i.e.*, Central European Encephalitis (CEE) and Russian Spring-Summer Encephalitis (RSSE) viruses), and Hepatitis C (HCV) viruses. Additional flaviviruses for use as the second flavivirus include Kunjin virus, Powassan virus, Kyasanur Forest Disease virus, and Omsk Hemorrhagic Fever virus. As is discussed further below, the second flavivirus sequences can be provided from two different second flaviviruses, such as two Dengue strains.

-7-

Fever 17D), the resulting chimeric virus is attenuated to a degree that renders it safe for use in humans.

Other features and advantages of the invention will be apparent from the following detailed description, the drawings, and the claims.

shadowed and black boxes, respectively. The chimeric YF/DEN3 genome was reconstituted by *in vitro* ligation of three fragments: the large BstBI-AatII portion of 5'3'/Den3/DXho plasmid, a PCR fragment containing the DEN3-specific part of 5.2/Den3 without the one nucleotide deletion (D1) digested with BstBI and EheI (an isoschizomer of NarI), and the large EheI-AatII fragment of YFM5.2 JE SA14-14-2. Ligation products were linearized with XhoI and then transcribed *in vitro* with SP6 RNA polymerase. Vero PM cells were transfected with *in vitro* RNA transcripts to recover the chimeric virus.

Fig. 31 is a schematic representation of an overview of construction of a YF/DEN4 chimera of the invention.

Fig. 32 is a schematic representation of a plasmid and fragment map relating to construction of a YF/DEN4 chimera of the invention.

Detailed Description

The invention provides chimeric flaviviruses that can be used in vaccination methods against flavivirus infection. Construction and analysis of chimeric flaviviruses of the invention, such as chimeras of yellow fever virus and Japanese Encephalitis (JE), Dengue types 1-4 (DEN 1-4), Murray Valley Encephalitis (MVE), St. Louis Encephalitis (SLE), West Nile (WN), Tick-borne Encephalitis (TBE), and Hepatitis C (HCV) viruses are described as follows.

Yellow fever (YF) virus is a member of the *Flaviviridae* family of small enveloped positive-strand RNA viruses. Flavivirus proteins are produced by translation of a single long open reading frame to generate a polyprotein, and a complex series of post-translational proteolytic cleavages of the polyprotein by a combination of host and viral proteases, to generate mature viral proteins (Amberg *et al.*, J. Virol. 73:8083-8094,

-13-

terminus of prM in the chimeras described below is central to the present invention. In particular, in the chimeras of the present invention, the length of the so-called "prM signal," which separates the two cleavage sites by 20 amino acids in YF (Figs. 1A and 1B), is substantially
5 maintained, to ensure polyprotein proteolytic processing and subsequent growth of chimeric viruses that are created in a YF backbone. A hydrophobic domain within this signal serves to direct the translocation of prM into the ER lumen, where efficient signalase cleavage occurs only after cleavage at the NS2B-NS3 site in the capsid protein (Amberg *et al.*,
10 J. Virol. 73:8083-8094, 1999; Figs. 1A and 1B).

In the chimeras of the present invention, only the regions encoding the membrane and envelope proteins (*i.e.*, the prME region) of a non-yellow fever flavivirus are used to replace the corresponding genes in a yellow fever virus clone. The prM signal of the yellow fever virus
15 backbone is maintained. Another method, described in a patent application by C.J. Lai, WO 93/06214, suggests a universal approach to constructing chimeric flaviviruses, involving cloning the prME region of a donor virus into the backbone of an acceptor virus, such that the prM signal sequence is contributed by the incoming prM protein gene. This
20 approach was illustrated using dengue 4 virus as the backbone (acceptor) and tick-borne encephalitis as the donor prME gene. As is illustrated in Fig. 2, the approach described in WO 93/06214 suggests that variability in this cloning strategy, with other chimeric models using flaviviruses as backbone, will have no effect on proper processing of the resulting
25 polyprotein. That is, that flavivirus prM signals are exchangeable when producing viable chimeric viruses. However, attempts to use this approach with YF as a backbone for the insertion of prME genes of dengue 2 virus to create a chimera in which dengue 2 sequences were

-15-

length and sequence of the YF prM signal in the chimeras of the invention. That is, preferably, the length of the prM signal is 20 amino acids. Less preferably, the length of the prM signal is 15, 16, 17, 18, 19, or more than 20 amino acids in length. Also, it is preferable that the amino acid
5 sequence of the YF prM signal is maintained in the chimeras of the invention, although this sequence can be modified using, for example, conservative amino acid substitutions. Preferably, the sequence of the prM signal is 100%, less preferably, 90%, 80%, 70%, 60%, 50%, or 40% identical to the YF prM signal.

10 As an example of construction of a chimera of the invention, Fig. 6 illustrates a YF/JE chimera in which the YF NS2B-NS3 protease recognition site is maintained. Thus, the recognition site for cleavage of the cytosolic from membrane-associated portions of capsid is homologous for the YF NS2B-NS3 enzyme. At the C/pr-M junction, the portion of the
15 signalase recognition site upstream of the cleavage site is that of the backbone, YF, and the portion downstream of the cleavage site is that of the insert, JE. At the E/NS1 junction, the portion of the signalase recognition site upstream of the cleavage site is similar to that of the insert, JE (four of five of the amino acids are identical to those of the JE
20 sequence), and the portion downstream of the cleavage site is that of the backbone, YF. It is preferable to maintain this or a higher level of amino acid sequence identity to the viruses that form the chimera. Alternatively, at least 25, 50, or 75% sequence identity can be maintained in the three to five amino acid positions flanking the signalase and NS2B-NS3 protease
25 recognition sites.

Also possible, though less preferable, is the use of any of numerous known signal sequences to link the C and pre-M or E and NS1 proteins of the chimeras (see, *e.g.*, von Heijne, Eur. J. Biochem. 133:17-21, 1983; von

-17-

ensuring stable expression of YF sequences and generation of RNA transcripts of high specific infectivity.

Our strategy for construction of chimeras involves replacement of YF sequences within the YF5'3'TV and YFM5.2 plasmids by the
5 corresponding JE sequences from the start of the prM protein (nucleotide 478, amino acid 128) through the E/NS1 cleavage site (nucleotide 2,452, amino acid 817). In addition to cloning of JE cDNA, several steps were required to introduce or eliminate restriction sites in both the YF and JE sequences to permit *in vitro* ligation. The structure of the template for
10 regenerating chimeric YF (C)/JE (prM-E) virus is shown in Fig. 7. A second chimera, encoding the entire JE structural region (C-prM-E) was engineered using a similar strategy. The second chimera was not able to generate RNA of high infectivity.

15 1.1 Molecular Cloning of the JE Virus Structural Region

Clones of authentic JE structural protein genes were generated from the JE SA14-14-2 strain (JE live, attenuated vaccine strain), because the biological properties and molecular characterization of this strain are well-documented (see, *e.g.*, Eckels *et al.*, Vaccine 6:513-518, 1988; JE SA14-
20 14-2 virus is available from the Centers for Disease Control, Fort Collins, Colorado and the Yale Arbovirus Research Unit, Yale University, New Haven, Connecticut, which are World Health Organization-designated Reference Centers for Arboviruses in the United States). JE SA14-14-2 virus at passage level PDK-5 was obtained and passaged in LLC-MK₂
25 cells to obtain sufficient amounts of virus for cDNA cloning. The strategy used involved cloning the structural region in two pieces that overlap at an *NheI* site (JE nucleotide 1,125), which can then be used for *in vitro* ligation.

-19-

(approximately 100 plaque-forming units/250 nanograms of transcript).

The JE sequence from nucleotides 1,108 to 2,471 was subcloned from several independent PCR-derived clones of pBluescript/JE into YFM5.2(*NarI*) using the unique *NsiI* and *NarI* restriction sites.

- 5 YF5'3'TV/JE clones containing the YF 5' untranslated region (nucleotides 1-118) adjacent to the JE prM-E region were derived by PCR amplification.

- To derive sequences containing the junction of the YF capsid and JE prM, a negative sense chimeric primer spanning this region was used
10 with a positive sense primer corresponding to YF5'3'TV nucleotides 6,625-6,639 to generate PCR fragments that were then used as negative sense PCR primers in conjunction with a positive sense primer complementary to the pBluescript vector sequence upstream of the *EcoRI* site, to amplify the JE sequence (encoded in reverse orientation in the pBluescript vector)
15 from nucleotide 477 (N-terminus of the prM protein) through the *NheI* site at nucleotide 1,125. The resulting PCR fragments were inserted into the YF5'3'TV plasmid using the *NotI* and *EcoRI* restriction sites. This construct contains the SP6 promoter preceding the YF 5'-untranslated region, followed by the sequence: YF (C) JE (prM-E), and contains the
20 *NheI* site (JE nucleotide 1,125) required for *in vitro* ligation.

1.3 Engineering YFM5.2 and YF5'3'TV to Contain Restriction Sites for in vitro Ligation

- To use the *NheI* site within the JE envelope sequence as a 5' *in vitro*
25 ligation site, a redundant *NheI* site in the YFM5.2 plasmid (nucleotide 5,459) was eliminated. This was accomplished by silent mutation of the YF sequence at nucleotide 5,461 (T→C; alanine, amino acid 1820). This site was incorporated into YFM5.2 by ligation of appropriate restriction

-21-

utilize the *NheI* site for *in vitro* ligation. The entire JE region in the Nakayama clone was sequenced to verify that the replaced cDNA was authentic (Table 1).

5 *1.5 Generation of Full-Length cDNA Templates, RNA Transfection, and Recovery of Infectious Virus*

Procedures for generating full-length cDNA templates are essentially as described in Rice *et al.* (The New Biologist 1:285-96, 1989; also see Fig. 7). In the case of chimeric templates, the plasmids

10 YF5'3'IV/JE(prM-E) and YFM5.2/JE are digested with *NheI/BspEI* and *in vitro* ligation is performed using 300 nanograms of purified fragments in the presence of T4 DNA ligase. The ligation products are linearized with *XhoI* to allow run-off transcription. SP6 transcripts are synthesized using 50 nanograms of purified template, quantitated by incorporation of ³H-

15 UTP, and integrity of the RNA is verified by non-denaturing agarose gel electrophoresis. Yields range from 5 to 10 micrograms of RNA per reaction using this procedure, most of which is present as full-length transcripts. Transfection of RNA transcripts in the presence of cationic liposomes is carried out as described by Rice *et al.* (*supra*) for YF 17D. In

20 initial experiments, LLC-MK₂ cells were used for transfection and quantitation of virus, since we have determined the permissiveness for replication and plaque formation of the parental strains of YF and JE. Table 2 illustrates typical results of transfection experiments using Lipofectin (GIBCO/BRL) as a transfection vehicle. Vero cell lines have

25 also been used routinely for preparation of infectious virus stocks, characterization of labeled proteins, and neutralization tests.

Amplification products from Vero cells were sent to the FDA (CBER) for preparation of the RMS in diploid, Fetal Rhesus lung cells. Fetal rhesus lung cells were received from the ATCC as cultured cells and

-23-

positions 177 and 264 occurred during subsequent passage, and appear to be genetically unstable between two SA14-14-2 virus passages in PHK and PDK cells, showing that this mutation is less critical for attenuation.

The nucleotide sequence of the E protein coding region of the RMS
5 was determined to assess potential sequence variability resulting from viral passage. Total RNA was isolated from RMS-infected Vero cells, reversed transcribed, and PCR amplified to obtain sequencing templates. Several primers specific for SA14-14-2 virus were used in individual sequencing reactions and standard protocols for cycle sequencing were
10 performed.

Sequence data revealed two single nucleotide mutations in the RMS E protein, when compared to the published SA14-14-2 JE strain sequence data. The first mutation is silent, and maps to amino acid position 4 (CTT to CTG); the second is at amino acid position 243 (AAA to GAA) and
15 introduces a change from lysine to glutamic acid. Both mutations identified are present in the sequence of the JE wild type strains Nakayama, SA14 (parent of SA14-14-2), and JaOArS982 (Sumiyoshi *et al.*, J. Infect. Dis. 171:1144-1151, 1995); thus, they are unlikely to contribute to virulence phenotype. We conclude that *in vitro* passage in
20 FRhL cells to obtain the RMS did not introduce unwanted mutations in the E protein.

1.7 Structural and Biological Characterization of Chimeric YF/JE Viruses

The genomic structure of chimeric YF/JE viruses recovered from
25 transfection experiments was verified by RT/PCR-based analysis of viral RNA harvested from infected cell monolayers. These experiments were performed to eliminate the possibility that virus stocks were contaminated during transfection procedures. For these experiments, first-pass virus was

-25-

JE-specific hyperimmune ascitic fluid (ATCC) and YF-specific purified IgG (monoclonal antibody 2E10). Significant differences in the 50% plaque reduction titer of these antisera were observed for the chimeras when compared to the control viruses in these experiments (Table 3). The YF/JE SA14-14-2 chimeric vaccine candidate, as well as the Nakayama chimera and SA14-14-2 viruses, were neutralized only by JE ascitic fluid, whereas YF 17D was neutralized in a specific fashion by YF ascites and the monoclonal antibody (Table 3). Thus, epitopes required for neutralization are expressed in the infectious chimeric YF/JE viruses, and are specific for the JE virus.

1.8 Growth Properties in Cell Culture

The growth capacity of the chimeras has been examined quantitatively in cell lines of both primate and mosquito origin. Fig. 8 illustrates the cumulative growth curves of the chimeras on LLC-MK₂ cells after low multiplicity infection (0.5 plaque-forming units/cell). In this experiment, YF5.2iv (cloned derivative) and JE SA14-14-2 (uncloned) viruses were used for comparison. Both chimeric viruses reached a maximal virus yield of approximately one log higher than either parental virus. In the case of the YF/JE SA₁₄-14-2 chimera, the peak of virus production occurred 12 hours later than the YF/JE Nakayama chimera (50 hours vs. 38 hours). The YF/JE Nakayama chimera exhibited considerably more cytopathic effects than the YF/JE SA14-14-2 chimera on this cell line.

A similar experiment was carried out in C6/36 cells after low multiplicity infection (0.5 plaque-forming units/cell). Fig. 8 also illustrates the growth kinetics of the viruses in this invertebrate cell line. Similar virus yields were obtained at all points used for virus harvest in

-27-

788; and Non-structural proteins: amino acids 789-3421); (nucleotide sequence of RMS; the coding sequence is from nucleotide 119 to nucleotide 10381)) with YF-Vax®, cells were grown to 90% confluency and infected with RMS or YF-Vax® at an MOI of 0.1 pfu. Since MRC-5
5 cells generally grow slowly, these cells were kept for 10 days post inoculation. Samples were frozen daily for 7-10 days and infectivity determined by plaque assay in Vero cells. YF-Vax® and the YF/JE chimera grew to modest titers in MRC-5 cells (Fig. 10). The peak titer was ~4.7 log₁₀ pfu for YF-Vax® achieved on the second day and was
10 slightly lower, 4.5 log₁₀ pfu, for the RMS after 6 days.

1.10 Growth Curve of YF/JE SA14-14-2 in FRhL cells with and without IFN-inhibitors

Fetal rhesus lung cells were obtained from the ATCC and
15 propagated as described for MRC-5 cells. Growth kinetics of the RMS were determined with and without interferon inhibitors.

Double-stranded RNA appears to be the molecular species most likely to induce interferon (IFN) in many virus infected cells. Induction of interferon apparently plays a significant role in the cellular defense against
20 viral infection. To escape cellular destruction, many viruses have developed strategies to down-regulate induction of interferon-dependent activities. Sindbis virus and vesicular stomatitis virus have been shown to be potent IFN inducers. Using chick embryo cells, mouse L cells, and different viral inducers of IFN, it was shown that 2-aminopurine (2AP)
25 and indomethacin (IM) efficiently and reversibly inhibit IFN action (Sekellick *et al.*, J. IFN Res. 5:651, 1985; Marcus *et al.*, J. Gen. Virol. 69:1637, 1988).

-29-

approximately one week post-inoculation. No mortality or illness was observed among mice receiving either the JE SA14-14-2 parent or the chimera. The inocula used for the experiments were titered at the time of injection and a subgroup of the surviving mice were tested for the presence
5 of neutralizing antibodies to confirm that infection had taken place. Among those tested, titers against the JE SA14-14-2 virus were similar for animals receiving either this strain or the chimera.

The results of additional experiments investigating the neurovirulence of the YF/JE SA14-14-2 chimera in mice are illustrated in
10 Table 4. In these experiments, all of the mice inoculated with YF5.2iv died within 7-8 days. In contrast, none of the mice inoculated with YF/JE SA14-14-2 died during two weeks of post-inoculation observation.

The results of experiments investigating the neuroinvasiveness and pathogenesis of YF/JE chimeras are illustrated in Table 5. In these
15 experiments, the chimeric viruses were inoculated into 3 week old mice at doses varying between 10,000 and 1 million plaque-forming units via the intraperitoneal route. None of the mice inoculated with YF/JE Nakayama or YF/JE SA14-14-2 died during three weeks of post-inoculation observation, indicating that the virus was incapable of causing illness after
20 peripheral inoculation. Mice inoculated with YF/JE SA14-14-2 developed neutralizing antibodies against JE virus (Fig. 13).

In additional experiments testing the neurovirulence phenotype and immunogenicity of the RMS, 4-week old ICR mice (n=5) were inoculated by the i.c. route with 0.03 ml of graded doses of the RMS or YF-Vax®
25 (Table 6). Control mice received only diluent medium by this route. Mice were observed daily and mortality rates were calculated.

Mice inoculated with YF-Vax® started to die on day 7 (Fig. 14A). The icLD₅₀ of unpassaged YF-Vax®, calculated by the method of Reed

-31-

induce significant titers of neutralizing antibodies 3 or 8 weeks post immunization, but antibodies were elicited at lower doses.

Very low doses ($1.4-2.4 \log_{10}$ PFU) of YF 17D vaccine elicited an immune response in mice 8 weeks after inoculation (Table 7). This result may indicate delayed replication of the vaccine in mice receiving low virus inocula. In contrast, the YF/JE SA14-14-2 chimeric vaccine in this dose range was not immunogenic. It is likely that the chimeric vaccine is somewhat less infectious for mice than YF 17D. However, when inoculated at an infective dose, the chimera appears to elicits a higher immune response. This may be due to higher replication in, or altered tropism for, host tissues. Animals that received two doses of JE-Vax® did not mount a significant antibody response. Only one animal in the 1:30 dose group developed a neutralizing titer of 1:10 eight weeks after immunization. This might be due to the route (s.c.) and dilution (1:30) of the vaccine.

1.13 Protection of YF/JE SA14-14-2 RMS immunized mice against challenge with virulent JE

The YF/JE SA14-14-2 RMS and other viruses were evaluated for immunogenicity and protection in C57/BL6 mice in collaboration with Dr. Alan Barrett, Department of Pathology, University of Texas Medical Branch, Galveston. Experimental groups are shown in Table 8. Ten-fold dilutions (10^2-10^5) of each virus were inoculated by the s.c. route into groups of 8 mice. Mice were observed for 21 days, at which time surviving animals were bled from the retro-orbital sinus and serum frozen for neutralization tests. The 50% immunizing dose (ID_{50}) for each virus and GMT was determined (see below).

1.14 Serological response

Sera from mice in groups shown in Table 8 were tested 21 days after immunization for neutralizing antibodies. N tests were performed as follows. Six-well plates were seeded with Vero cells at a density of 10^6 cells/well in MEM alpha containing 10% FBS, 1% nonessential amino acids, buffered with sodium bicarbonate. One hundred μ l of each test serum (inactivated at 60°C for 30 minutes) diluted two-fold was mixed with an equal volume of virus containing 200-300 PFU. The virus-serum mixtures were incubated at 4°C overnight and 100 μ l added to each well after removal of growth medium. The plates were overlaid after 1 hour incubation at 37°C with 0.6% agarose containing 3% fetal calf serum, 1% L-glutamine, 1% HEPES, and 1% pen-strep-amphotericin mixed 1:1 with 2x M199. After 4 days of incubation at 37°C, 5% CO₂, a second overlay containing 3% Neutral red was added. After appearance of plaques, the monolayer was fixed with 1% formaldehyde and stained with crystal violet. The plaque reduction titer is determined as the highest dilution of serum inhibiting \geq 50% of plaques compared with the diluent-virus control.

Results are shown in Table 10 and Fig. 16. NT antibody responses in mice immunized with the YF/JE SA14-14-2 chimera showed a dose response and good correlation with protection. At doses of 4-5 logs, the chimeric vaccine elicited higher N antibody responses against JE than either SA14-14-2 virus or wild-type Nakayama virus. Responses were superior to those elicited by YF-Vax® against YF 17D virus. No prozone effect was observed in animals receiving the chimera or infectious-clone derived YF 5.2iv; responses at the highest vaccine dose (5 logs) were higher than at the next lower dose (4 logs). In contrast, mice that received

-35-

4.7 log₁₀) pfu should not have viremia greater than 165,000 pfu/ml (approximately 16,500 mLD₅₀). None of the monkeys in the experiments had viremia of more than 15,000 pfu/ml, despite receiving 6 log₁₀ pfu of the RMS.

- 5 Neutralizing antibody titers were measured at 2 and 4 weeks post inoculation (Fig. 18). All monkeys seroconverted and had high titers of neutralizing antibodies against the inoculated viruses. The level of neutralizing antibodies in 2 of 3 monkeys in both groups exceeded a titer of 1:6,400 (the last dilution of sera tested) at 4 weeks post inoculation.
- 10 The geometric mean antibody titers for ChimeriVax were 75 and 3,200 after 2 and 4 weeks respectively and were 66 and 4971 for the YF-Vax® for the same time points (Table 11).

- Histopathological examination of coded specimens of brain and spinal cord were performed by an expert neuropathologist (Dr. I. Levenbook, previously CBER/FDA), according to the WHO biological standards for yellow fever vaccine. There were no unusual target areas for histopathological lesions in brains of monkeys inoculated with ChimeriVaxTM-JE. Mean lesion scores in discriminator areas were similar in monkeys inoculated with YF-Vax® (0.08) and monkeys inoculated with
- 20 a 100-fold higher dose of ChimeriVaxTM-JE (0.07). Mean lesion scores in discriminator + target areas were higher in monkeys inoculated with YF-Vax® (0.39) than in monkeys inoculated with a 100-fold higher dose of ChimeriVaxTM-JE (0.11). These preliminary results show an acceptable neurovirulence profile and immunogenicity for ChimeriVaxTM-JE vaccine.
- 25 A summary of the histopathology results is provided in Table 22.

-37-

1.18 Position 138 on the E protein

A single mutation of an acidic residue glutamic acid (E) to a basic residue, lysine (K) at position 138 on the E protein of JE virus results in attenuation (Sumiyoshi *et al.*, J. Infect. Dis. 171:1144, 1995). Experiments
5 were carried out to determine whether the amino acid at position 138 of the JE envelope protein (K in the vaccine chimera and E in the virulent Nakayama chimera) is a critical determinant for neurovirulence in mice. Chimeric YF/JE SA14-14-2 (K 138----> E) virus containing the single reversion of

10 K---->E at position 138 was generated from an engineered cDNA template. The presence of the substitution and the integrity of the entire E protein of the resulting virus was verified by RT/PCR sequencing of the recovered virus. A standard fixed-dose neurovirulence test of the virus was conducted in 4-week-old outbred mice by i.c. inoculation with 10^4 pfu
15 of virus. The YF/JE SA14-14-2 and YF/JE Nakayama chimeric viruses were used as controls. The virulence phenotype of YF/JE SA14-14-2 (K-->E) was indistinguishable from that of its attenuated parent YF/JE SA14-14-2 in this assay, with no morbidity or mortality observed in the mice during the observation period (Fig. 19).

20 We conclude that the single mutation at position 138 to the residue found in the JE-Nakayama virus does not exert a dominant effect on the neurovirulence of the YF/JE SA14-14-2 chimera, and that one or more additional mutations are required to establish the virulent phenotype.

25 1.19 Other putative attenuation loci

Additional experiments to address the contributions of the other 6 residues (mentioned above) using the format described here were

-39-

a selective advantage by competing more effectively with the original vaccine virus and take over the culture. Therefore, mutant strains of the vaccine that grow better than the original vaccine may be selected by subculturing *in vitro*. One concern that addressed experimentally is
5 whether such selective pressures might lead to mutant vaccine viruses with increased virulence.

In theory, molecular evolution should occur more rapidly for RNA viruses than DNA viruses because viral RNA polymerases have *higher* error rates than viral DNA polymerases. According to some
10 measurements, RNA virus mutation rates approach one mutation per replication event. This is why an RNA virus can be thought of as a family of very closely related sequences (or "quasispecies"), instead of a single unchanging sequence (a "classical species").

Two different approaches can be taken to determine the sequence of
15 an RNA virus:

1) purify viral genomic RNA from the culture supernatant, reverse-transcribe the RNA into cDNA and sequence this cDNA. This is the approach we have taken. It yields an averaged, or consensus sequence, such that only mutations which represent a large proportion (roughly,
20 >20%) of the viruses in the culture can be detected.

2) Alternatively, cDNA can be cloned and individual clones sequenced. This approach would reveal the quasispecies nature of the vaccine by identifying individual mutations (deviations from the consensus sequence) in some proportion of the clones.

-41-

from P1 to P10, but at P18 it is back to the value seen at P8. One possible explanation for this observation is that a mutant bearing the H394R mutation gradually became as abundant as the original virus but was then out-competed by a new mutant bearing other mutations not present in the M or E genes and therefore, only detected as a rebound in the A/G ratio. We are reproducing these results by doing a second passaging experiment under identical conditions. It must also be noted that duplicate samples of viral genomic RNA were isolated, reverse-transcribed, amplified, and sequenced in parallel for each passage examined. Reported results were seen in both duplicate samples, arguing against any RT-PCR artifacts obscuring the data.

These observations show that minor genetic changes (one nucleotide substitution in the entire envelope E and M genes) have occurred in the JE sequences of the chimeric vaccine upon passaging, but that selective pressures did not lead to the loss of any of the attenuating mutations of the E gene.

1.24 Neurovirulence phenotype of passages 10 and 18

Groups of five female ICR mice, 3 to 4 weeks-old, received 30 μ l i.c. of undiluted, P1, P10, or P18, as well as 30 μ l of 10-fold dilutions. None of the mice injected with P1, P10, or P18 (doses $\geq 7 \log_{10}$ pfu) showed any sign of illness over a five week period. As determined by back-titration, the doses administered (pfu) were measured as shown in Table 17.

-43-

Finally, the sequences of the entire genomes of the RMS and p18 were determined and found to be identical, except for the E-H394 mutation (Table 25). There are 6 nucleotide (NT) differences (NT positions are shaded) between the published YF 17D sequences and RMS shown in bold letters. Changes in positions 5461, 5641, 8212, and 8581 are silent and do not result in amino acid substitution, whereas changes in positions 4025 (ns2a) and 7319 (ns4b) result in amino acid substitutions from V to M and from E to K, respectively. Amino acid Methionine (M) at position 4025 is unique for RMS and is not found in any other YF strains, including parent Asibi virus and other yellow fever 17D strains (e.g., 204, 213, and 17DD), whereas Lysine (K) at position 7319 is found in 17D204F, 17D213, and 17DD, but not in 17D204US or Asibi strain. Since the RMS is more attenuated than YF 17D with respect to neurovirulence, and thus has better biological attributes as a human vaccine, it is possible that the amino acid differences at positions 4025 and 7319 in the nonstructural genes of the yellow fever portion of the chimeric virus contribute to attenuation. Other workers have shown that the nonstructural genes of yellow fever virus play an important role in the attenuation of neurovirulence (Monath, "Yellow Fever," in Plotkin *et al.*, (Eds.), *Vaccines*, 2nd edition, W.B. Saunders, Philadelphia, 1998).

1.27 Experiment to Identify Possible Interference Between YF 17D and YF/JE SA14-14-2

It is well-established that yellow fever virus encodes antigenic determinants on the NS1 protein that induce non-neutralizing, complement-fixing antibodies. Passive immunization of mice with monoclonal anti-NS1 antibodies confers protection against challenge.

-45-

groups (n=8) were immunized with a single dose of YF-Vax® (0.1 ml of a 1:2 dilution of reconstituted vaccine, containing 4.4 log₁₀ pfu, previously determined to induce the highest immune response to YF virus). Six groups (n=4) of mice (similar age, 3-4 weeks old) were kept as controls for 5 booster doses at 3, 6, and 12 months post primary immunization.

All mice were bled 4 and 8 weeks after primary immunization and their neutralizing antibody titers were measured against homologous viruses in a plaque assay. 21/24 (87.5%) of the animals immunized with a single dose of ChimeriVax™-JE developed anti-JE neutralizing antibodies 10 1 month after immunization; at 2 months, 18/24 (75%) were seropositive. Geometric mean increased somewhat between 1 and 2 months post inoculation. In contrast, only 25%-33% of the mice immunized with YF-Vax® seroconverted and antibody responses were low. These results show that YF 17D virus and chimeric viruses derived from YF 17D are 15 restricted in their ability to replicate in the murine host; however, when the envelope of JE virus is incorporated in the chimeric virus, the ability to replicate in and immunize mice is apparently enhanced. Mice receiving two doses of JE-Vax® developed high neutralizing titers against parent Nakayama virus, and titers increased between 1 and 2 months post 20 immunization.

1.29 Secondary Immunization of ChimeriVax™JE and JE-Vax® Immunized Mice With YFVax®

Three months and six months after primary immunization with 25 ChimeriVax-JE, mice were inoculated with YF-Vax® (1:2 dilution of a human dose containing 4.4 log₁₀ pfu). Control mice not previously immunized and of identical age received ChimeriVax™JE only or

-47-

responded 6 months later to immunization with YF-Vax® and that the GMT and range of neutralizing antibody titers were similar to controls suggests that the chimeric vaccine imposed no significant barrier to yellow fever immunization.

5

2.0 Construction of cDNA Templates for Generation of Yellow Fever/Dengue (YF/DEN) Chimeric Viruses

Derivation of chimeric Yellow Fever/Dengue (YF/DEN) viruses is described as follows which, in principle, is carried out the same as
10 construction of the YF/JE chimeras described above. Other flavivirus chimeras can be engineered with a similar strategy, using natural or engineered restriction sites and, for example, oligonucleotide primers as shown in Table 20.

15 2.1 Construction of YF/DEN Chimeric Virus

Although several molecular clones for dengue viruses have been developed, problems have commonly been encountered with stability of viral cDNA in plasmid systems, and with the efficiency of replication of the recovered virus. We chose to use a clone of DEN-2 developed by Dr.
20 Peter Wright, Dept. of Microbiology, Monash University, Clayton, Australia, because this system is relatively efficient for regenerating virus and employs a two-plasmid system similar to our own methodology. (See Table 21 for a comparison of the sequences of Dengue-2 and YF/Den-2₂₁₈ viruses; YF/Den-2₂₁₈ contains the nucleotide and amino acid sequences of
25 PUO-218. The NGC and PR-159 strains, which are also listed in Table 21, are other wild strains of dengue that differ from PUO-218 and can be used in the chimeras of the invention.) The complete sequence of this

-49-

sequence 5' untranslated and capsid sequence and a 3' *TfiI* site, together with a 3' PCR fragment beginning with a *TfiI* site at the amino terminus of the dengue-2 prM protein and the flanking dengue-2 prM protein sequence, were ligated into the YF5'3'TV plasmid after intermediate
5 construction in pBluescript. Screening with *TfiI* was used to confirm correct assembly of the chimeric junction in the final plasmid YF5'3'TV/DEN(prM-E).

2.2 Construction of Chimeric YF/DEN Viruses Containing Portions of 10 Two DEN Envelope Proteins

Since neutralization epitopes against DEN viruses are present on all three domains of the E protein, it is possible to construct novel chimeric virus vaccines that include sequences from two or more different DEN serotypes. In this embodiment of the invention, the C/prM junction and
15 gene encoding the carboxyl terminal domain (Domain III) of one DEN serotype (*e.g.*, DEN-2) and the N-terminal sequences encoding Domains I and II of another DEN serotype (*e.g.*, DEN-1) are inserted in the YF 17D cDNA backbone. The junctions at C/prM and E/NS1 proteins are retained, as previously specified, to ensure the infectivity of the
20 double-chimera. The resulting infectious virus progeny contains antigenic regions of two DEN serotypes and elicits neutralizing antibodies against both.

2.3 Transfection and Production of Progeny Virus

25 Plasmid YF5'3'TV/DEN(prME) and YFM5.2/DEN(E'-E) were cut with *SphI* and *AatII* restriction enzymes, appropriate YF and dengue fragments were isolated and ligated *in vitro* using T4 DNA ligase. After

2.5 Growth Kinetics in Cell Culture

The growth kinetics of the YF/Den-2 chimera were compared in Vero and FeRhL cells (Fig. 16). Cells were grown to confluency in tissue culture flask (T-75). FeRhL cells were grown in MEM containing Earle's salt, L-Glu, non-essential amino acids, 10% FBS and buffered with sodium bicarbonate, and Vero cells were grown in MEM-Alpha, L-Glu, 10% FBS (both media purchased from Gibco/BRL). Cells were inoculated with YF/Den2 at 0.1 MOI. After 1 hour of incubation at 37°C, medium containing 3% FBS was added, and flasks were returned to a CO₂ incubator. Every 24 hours, aliquots of 0.5 ml were removed, FBS was added to a final concentration of 20%, and frozen for determination of titers in a plaque assay. Forty eight hours post infection CPE was observed in FeRhL cells and reached 100% by day 3. In Vero cells, CPE was less dramatic and did not reached 100% by the completion of the experiment (day 5). As shown, the YF/Den2 reached its maximum titer (7.4 log₁₀ pfu/ml) by day 3 and lost about one log (6.4 log₁₀ pfu/ml) upon further incubation at 37°C, apparently due to death of host cells and virus degradation at this temperature. The maximum virus titer in Vero cells was achieved by day 2 (7.2 log₁₀ pfu/ml) and only half log virus (6.8 log₁₀ pfu/ml) was lost on the following 3 days. This higher rate of viable viruses in Vero cells may be explained by incomplete CPE observed in these cells. In sum, the chimera grows well in approved cell substrate for human use.

-53-

Although mouse neurovirulence does not predict virulence/attenuation of dengue viruses for humans, it is important to determine the neurovirulence of a YF/Den-2 chimeric virus. YF 17D retains a degree of neurotropism for mice, and causes (generally subclinical) encephalitis in monkeys after IC inoculation. For vaccine development of a den/YF chimera it will be necessary to show that the construct does not exceed YF 17D in neuroinvasiveness and neurovirulence. Ultimately safety studies in monkeys will be required. In initial studies, we determined if insertion of the prME of the PUO218 into YF 17D vaccine strain will affect its neurovirulence for suckling mice (Table 24). Groups of 3, 5, 7, and 9 days old suckling mice were inoculated by the I.C. route with 10,000 pfu of YF/Den-2 or YF/JE SA14-14-2 chimera and observed for paralysis or death for 21 days. For controls similar age groups were inoculated either sham with medium (I.C. or I.P.) or with 1,000 pfu of unpassaged commercial YF vaccine (YF-Vax) by the I.P. route (it is not necessary to inoculate suckling mice with YF-Vax by the I.C. route because we have previously shown that this vaccine is virulent for 4-weeks old mice by this route).

As shown in Fig. 22, all suckling mice (3 to 7 days old) inoculated by the I.C. route with the YF/Den2 chimera died between 11 and 14 days post inoculation, whereas 8 out of 10 suckling mice (9 days old) survived. Similarly, all suckling mice (3-5 days old) inoculated with YF-Vax by the I.P. route, with a dose which was 10-fold lower than the YF/Den2 chimera, died between 11 to 13 days post inoculation (Fig. 23). All nine day old, as well as 8 out of 9 seven day old, mice inoculated with the YF-Vax survived. Similar results to the YF/Den2 chimera obtained with suckling mice inoculated with the YF/JE SA14-14-2 chimera.

-55-

viruses (produced by tissue culture passage or recombinant DNA technology). Although some of these candidates have shown promise in preclinical and human volunteers, development of a successful dengue vaccine remained to be implemented.

- 5 Evaluating the immunogenicity and protective efficacy of the YF/Den2 chimera in monkeys should shed light on selection of appropriate prME genes (from wild type or attenuated strain) for construction of all 4 serotypes of chimeric dengue viruses.

10 2.7 *Stability of prME genes of ChimeriVax™-D2 virus in vitro*

The ChimeriVax™-D2 virus at passage 2 post transfection was used to inoculate a 25 cm² flask of Vero cells. Total RNA was isolated and the complete nucleotide sequence of the ChimeriVax™-D2 was determined (P3) and compared to the published sequence of the YF 17D virus (Rice *et al.*, Science 229:726-733, 1985). There was one nucleotide difference: at position 6898 there was an A in the chimera (P3), which was a C in the 17D nucleotide sequence. No difference in the prME region was found when the sequence of ChimeriVax™-D2 was compared to its parent dengue 2 virus (PUO218 strain). Also, no mutations were found in the prME genes of the chimera upon 18 passages in VeroPM cells. Within the YF genes, however, there was one silent mutation in position 6910 (C to A), and at position 3524 the P18 virus appeared to be heterozygous (both parent nucleotides, G and mutant A, were present). This would translate into a mixture of E and K amino acids at position 354 of the NS1 protein.

Similar to the passage 3 virus, the passage 18 virus was not neurovirulent for 4 week old outbred mice inoculated by the IC route (5

-57-

rhesus monkeys, which lasts between 3-6 days. Attenuation of dengue 2 viruses can therefore be estimated by comparing the level and duration of viremia with reference wild-type strains. These experiments clearly showed that core and non-structural proteins of YF 17D virus present in
5 ChimeriVax™-D2 do not interfere with ChimeriVax™-D2 immunization.

2.9 Dose response effectiveness of ChimeriVax™-D2 in monkeys.

The goals of this experiment were to (i) determine the viremia profile of the vaccine candidate, using YF 17D and wild type dengue 2
10 virus controls, (ii) compare neutralizing antibody responses to the vaccine candidate and wildtype virus, and (iii) determine minimum dose required for protection against challenge with wild type dengue-2 virus. It was anticipated that these experiments would define the viremia profile of the ChimeriVax™-D2 virus in non-YF immune monkeys, and would
15 determine whether immunization with a single dose results in protection of animals against challenge with a wild type dengue 2 virus. Protection in these experiments is defined as reduction of viremia in test monkeys compared to control viruses.

As is shown in table 28, all monkeys became viremic, and the
20 duration of viremia was dose-dependent. The peak level of viremia for ChimeriVax™-D2 was between 1.3 to 1.6 log₁₀ pfu, which was significantly lower than that of the wild type dengue virus (3.6 log₁₀ pfu).

All monkeys developed anti-dengue 2 neutralizing antibodies by day 15. Lower dose of the vaccine resulted in lower GMTs, however, by
25 day 30 post-immunization, all monkeys developed high titers of neutralizing antibodies, independent of the dose they received. Upon challenge, no viremia was detected in any immunized monkeys,

-59-

Individual mosquitoes were triturated in 1 ml of M199 media (Gibco BRL, Grand Island, New York) supplemented with 5% fetal calf serum, clarified by brief centrifugation, and then titrated in Vero cells to monitor virus replication.

5 Both JE SA14 and JE SA14-14-2 viruses replicated in *Cx. tritaeniorhynchus* following IT inoculation, reaching titers at day 14 of 6.7 and 6.0 log₁₀ pfu/mosquito, respectively (Figure 24A). Additionally, IFA conducted on head squashes from JE SA14 and JE SA14-14-2-inoculated *Cx. tritaeniorhynchus* mosquitoes was positive for detection of JE virus
10 antigen. In contrast, YF 17D and ChimeriVax™-JE did not replicate in *Cx. tritaeniorhynchus* mosquitoes. Virus titers declined rapidly following inoculation, and no virus was detectable by plaque titration assay in YF 17D or ChimeriVax™-JE-inoculated mosquitoes by days 1 and 2, respectively (Figure 24A). IFA analysis of head squashes from *Cx. tritaeniorhynchus* mosquitoes inoculated with ChimeriVax™-JE or YF
15 17D was negative for JE or YF virus antigens, supporting our observation that neither the chimera nor YF 17D replicate in this mosquito species.

ChimeriVax™-JE did replicate in IT-inoculated *Ae. albopictus* mosquitoes, reaching a titer of 5.2 log₁₀ pfu/mosquito at day 18 (Figure
20 24B) and IFA results were weakly positive for both JE virus and YF virus antigens. The JE SA14 and JE SA14-14-2 viruses also replicated in *Ae. albopictus* mosquitoes, reaching maximum titers of 6.3 and 6.0 log₁₀ pfu/mosquito, respectively. YF 17D virus did not replicate to high titers in *Ae. albopictus* mosquitoes, however, a low level of detectable virus was
25 maintained (3.8 log₁₀ pfu/mosquito at day 18) (Figure 24B) and IFA-stained head squashes were weakly positive for YF virus antigen. ChimeriVax™-JE and YF 17D inoculated IT into *Ae. aegypti* mosquitoes

-61-

Figures 25B and 25C illustrate growth of the viruses in orally exposed *Ae. albopictus* and *Ae. aegypti* mosquitoes, respectively. Only JE SA14 and JE SA14-14-2 viruses successfully infected and replicated in these species. For example, in *Ae. aegypti* mosquitoes on day 15, the titers of JE SA14 and JE SA14-14-2 viruses were 5.4 and 5.5 log₁₀ pfu, respectively. In contrast, mosquitoes that had ingested 4.7 log₁₀ pfu/mosquito of YF17D virus or 4.5 log₁₀ pfu/mosquito of ChimeriVax™-JE virus failed to become infected.

In a separate experiment, *Ae. aegypti* and *Ae. albopictus* mosquitoes were orally exposed to JE SA14-14-2, YF 17D, and ChimeriVax™-JE viruses and processed after 22 days extrinsic incubation to permit growth to maximum virus titers. The results of this experiment are summarized in Table 30. Only JE SA14-14-2 virus was detectable in mosquitoes. Because ChimeriVax™-JE did not grow in any of the mosquito species tested, transmission studies were not performed.

Viruses recovered from *Ae. Albopictus* after IT or oral inoculation, or from *Ae. Aegypti* after IT inoculation, were identical to their parent ChimeriVax™-JE virus (Vero2FrhL1) in the prME region.

2.13 Amplification and sequencing of the "late replicating"

ChimeriVax™-JE viruses isolated from mosquitoes

Ae. albopictus mosquitoes inoculated with ChimeriVax™-JE by IT or oral routes and *Ae. aegypti* inoculated with ChimeriVax™-JE by IT route, were harvested on day 15 post-inoculation. After triturating in 1 ml of M199 (supplemented with 5% fetal calf serum), samples were clarified by centrifugation, filtered through a 0.2 micron filter, and used to inoculate a T-25 cm² flask of VeroPM cells, passage 144 (0.5 ml/flask). After 1

-63-

moderate growth following IT inoculation into *Ae. aegypti* and *Ae. albopictus* mosquitoes, reaching titers of 3.6-5.0 log₁₀ pfu/mosquito. There was no change in the virus genotype associated with replication in mosquitoes. Similar results were observed in mosquitoes of all three
5 species that were IT inoculated or had orally ingested the YF 17D vaccine virus. In contrast, all mosquitoes either IT inoculated with, or orally fed, wild type and vaccine JE viruses became infected, reaching maximum titers of 5.4-7.3 log₁₀ pfu/mosquito. The growth of ChimeriVax™-D2 in both *Ae. albopictus* and *Ae. aegypti* mosquitoes inoculated by IT or oral
10 routes was also significantly lower than its parent wild type dengue 2 and YF17D vaccine viruses.

These results showed that ChimeriVax™-JE and ChimeriVax™-D2 viruses are restricted in their abilities to infect and replicate in these mosquito vectors. The low viremia caused by the viruses in primates and
15 poor infectivity for mosquitoes are safeguards against secondary spread of the vaccine virus.

3.0 Construction of ChimeriVax™ YF/DEN-1

A yellow fever/dengue 1 (YF/DEN-1) chimeric virus was
20 constructed using a novel technology, which differs from the approaches used to construct Yellow fever/Japanese encephalitis (YF/JE) chimeric viruses as described by Chambers *et al.* (J. Virol. 73:3095-4101, 1999; see above), and the construction of YF/DEN-4 chimera (see below). We used the same two plasmid system used to create YF/DEN-4. These plasmids
25 first encoded the yellow fever (YF) genome as created by Rice *et al.* (New Biol. 1:285-296, 1989). Later, the structural membrane precursor and envelope protein genes, *i.e.*, the prME region, of the YF genome plasmids

-65-

full-length virus cDNA template for RNA transcription. All steps involving cDNA fragments, plasmids, and PCR products were carried out in a BL-2 lab designated for recombinant DNA work. Steps involving manipulations of infectious RNA and virus were carried out in a limited
5 access BL-2+ virus lab.

3.1 Amplification of Dengue 1 sequence

Dengue 1 cDNA was synthesized from RNA using the Superscript IITM method. All primers for this experiment were synthesized by Life
10 Technologies and are listed in Table 31. Upon arrival as lyophilized material, they were dissolved to 250 μ M stock solutions using RODI-water. From this, 25 μ M working solutions were made. The fragment encoding the SP6 promoter and the yellow fever capsid (Fragment A) was amplified using XL-PCR Reaction KitTM
15 (Perkin-Elmer Part#N808-0192), with 0.5 μ l (250 ng) of pYF5'3TV plus 3.5 μ l RODI-water as template and primers 1 and 2 (see Table 31). The fragment encoding dengue 1 prM and 5' end of E (Fragment B) was amplified using the XL-PCR Reaction KitTM (Perkin-Elmer Part#N808-0192) and primers 3 and 4. The fragment encoding the 3' end
20 of the Dengue 1 envelope gene (Fragment F) was amplified using the same protocol, but with primers 5 and 7. The fragment encompassing the YF portion of pYFM5.2 (Fragment G) was amplified using the same protocol, but with primers 8 and 9 and 1 μ l of pYFM5.2/2 with 39 μ l water. The PCR for fragments F and G required an annealing temperature of 50°C
25 and an extension time of 6.5 minutes. The PCR reaction was performed using the following master mixes for each reaction.

-67-

Fragment	Approximate Size (kb)
A	0.94
B	0.65
F	1.3
G	6.0

Forty μ l of each fragment was then separated on a 1% Agarose/TAE gel and purified using the QIAquick Gel Extraction Kit (Qiagen cat#28704). Next, the concentrations of the purified fragments were determined by UV absorption using 1:40 dilutions in RODI-water.

Sample	A280	A260	280/260	260/280	Concentration
Fragment A	0.0116	0.0260	0.4453	2.2457	52 ng/ μ l
Fragment B	0.0076	0.0202	0.3782	2.6440	40.4 ng/ μ l
Fragment F	0.0160	0.0335	0.4785	2.0898	67 ng/ μ l
Fragment G	0.0199	0.0380	0.5242	1.9076	76 ng/ μ l

3.2 Recombinant PCR

To create a fusion between the yellow fever capsid and DEN-1 prM, a recombinant PCR technique known as overlap-extension PCR was used to create Fragment E. The same basic UM and LM were used, and primers 1 and 4 replaced earlier primers. The same approach was used to create a fusion between fragment F and G, resulting in fragment H. For this, primers 5 and 9 were used. The cDNA mixes were as follows:

	Fragment E	Fragment B control	Fragment A control
H ₂ O	37.82 μ l	38.97 μ l	38.85 μ l
Fragment A	1.15 μ l	0 μ l	1.15 μ l
Fragment B	1.03 μ l	1.03 μ l	0 μ l
Volume	40 μ l	40 μ l	40 μ l

-69-

The capsid-prME fusion was cloned into the yellow fever plasmid needed, and after digestion of the purified Fragment E, as well as pYF5'3'IV, with the appropriate enzymes. The digested plasmid resulted in two bands. Lower bands seen contain a fragment of Japanese encephalitis virus equivalent to Fragment E. All restriction enzymes, buffers, and 100x BSA were from New England Biolabs. All the digestions were incubated in a Perkin-Elmer 480 cyclor set to hold at 37°C overnight.

Fragment E Digest

10	Fragment E (600 ng)	5.8 µl
	NEB Buffer 4	4 µl
	10x BSA	4 µl
	H ₂ O	24.2 µl
	Not I	1 µl

	Volume	40 µl

pYFMIV5'3' Digest

	pYFMIV5'3' (1.02 µg)	2 µl
20	NEB Buffer 4	2 µl
	10x BSA	2 µl
	H ₂ O	12 µl
	Not I	1 µl
	Nhe I	1 µl
25	Volume	20 µl

3.4 Vector Dephosphorylation

Calf Intestinal Phosphatase (CIP) from New England Biolabs (cat#290S) was diluted 1:10 in 1x CIP Buffer. One µl of this dilution was

-71-

pYFM-5'3' Control Ligation

	Fragment E (97.5 ng)	0 μ l
	pYFM5'3' (50 ng)	3.0 μ l
	H ₂ O	14 μ l
5	10x T4 ligase buffer	2 μ l
	T4 DNA ligase	1 μ l
	Volume	20 μ l

3.7 Transformations

- 10 Ligation reactions were individually transformed into *E. coli* strain MC1061 (recA-). Briefly, an aliquot of MC1061 was removed from storage at -80°C and allowed to thaw on ice for one to two minutes. 0.9 ml of cold 0.1 M CaCl₂ was added to the cells. One hundred μ l of cells was aliquoted into three 12 ml culture tubes on ice. Ten μ l of each
- 15 ligation reaction was added to each culture tube, leaving the third tube as a no DNA control. Culture tubes were left on ice for 30 minutes. The tubes were heat shocked in a water bath at 42°C for 45 seconds, and then were put back on ice for 2 minutes. 0.9 ml SOC medium was added to each culture tube and incubated at 225 pm in a shaking incubator at 37°C for 1
- 20 hour. Each transformation mix was aliquoted into 1.5 ml microcentrifuge tubes. One hundred μ l of each mix was spread onto LB/Agar-Amp (100 μ g/ml) plates and labeled as "neat." Each tube was spun at 14,000 rpm in a microcentrifuge for 2-3 seconds to pellet the cells. The supernatant was poured into the waste container and the pellet resuspended in the residual
- 25 broth by pipetting up and down. This material was plated (approximately 100 μ l) onto LB/Agar-Amp (100 μ g/ml) plates and labeled as 10x. All plates were inverted in a 37°C incubator overnight.

-73-

3.9 Glycerol Stocks

One hundred twenty ml of LB-Amp (100 µg/ml) was then inoculated from a patch pYD1-5'3'/2 and shaken at 225 rpm overnight at 37°C. Two x 1 ml of this culture was then spun at 14 Krpm for 2-3
5 seconds to pellet the cells. These were resuspended in LB-Glycerol (30%) and frozen at -80°C.

3.10 MIDI Plasmid Preparation

Qiagen Midi-Prep was performed on the remaining culture using
10 the following modified protocol.

1. Spin 150 ml of each culture at 7 Krpm in GSA rotor for 10 minutes to pellet.
2. Decant Supernatant
3. Resuspend pellet in 4 ml P1 buffer; Transfer to 50 ml Falcon tube.
- 15 4. Rinse centrifuge bottle with 1 ml P1 buffer and transfer to the Falcon tube.
5. Add 5 ml P2 buffer; invert gently; incubate 5 minutes at room temperature or until lysed (no more than 12 minutes).
6. Add 5 ml P3 buffer; mix as above; incubate 10 minutes on ice.
- 20 7. Transfer supernatant to Qiagen Syringe Filter; Let sit for 10 minutes.
8. Equilibrate Q-100 tip with 4 ml QBT.
9. Gently push plunger to filter supernatant onto Q-100 tip.
10. Allow to drain by gravity.
11. Wash with 10 ml 2x QC.

-75-

Both reactions were incubated in a 37°C block overnight. Five µl of each digestion was run out on a 1.5% Agarose/TAE gel to check for complete digestion. The digestion was then incubated at 65°C for 20 minutes to inactivate the enzyme. 2.5 µl Bst BI (NEB) was added to each reaction and placed at 65°C overnight. The expected results of the digest are as follows:

10	pYD1-5'3'/2	Fragment H
	5.6 kb	7.2 kb
	0.14 kb	0.1 kb

The largest band from each reaction was gel excised and the UV concentration was determined (as previously described).

15	Sample	A280	A260	280/260	260/280	Concentration
	pYD1-5.2 fragment	0.0089	0.0154	0.5777	1.7309	30.8 ng/µl
	Fragment H	0.0020	0.0018	1.1333	0.8824	3.6 ng/µl

There was not enough fragment H for the ligation. Another 50 µl of fragment H was cleaned over a Qiagen Qiaquick column and digested with Aat II and Bst BI as described previously. The digested fragment was then gel excised as before and the UV concentration determined.

25	Sample	A280	A260	280/260	260/280	Concentration
	Fragment H	0.0000	0.0021	0.0000	NA	4.2 ng/µl

-77-

3.15 Linear cDNA extraction (RNase free phase)

1. Add H₂O to 100 µl total volume.
2. Add 1/10th volume 3 M Sodium Acetate
3. Add 100 µl Phenol/Chloroform/Isoamyl Alcohol and spin at 14 Krpm .
- 5 for 5 minutes in a microcentrifuge. Extract upper layer into RNase-free 1.5 ml tube. Repeat once.
4. Add 100 µl RNase-free Chloroform. Spin at 14 Krpm for 5 minutes in a microcentrifuge. Extract upper layer into RNase-free 1.5 ml tube. Repeat once.
- 10 5. Add 200 µl 100% RNase-free ethanol.
6. Place on dry-ice/ethanol bath for 10 minutes.
7. Spin at 14 Krpm for 20 minutes in a microcentrifuge.
8. Wash with 200 µl 70% ethanol (RNase-free).
9. Repeat 70% ethanol wash two more times.
- 15 10. Dry in Speed-Vac for 8 minutes (or until no more ethanol is present).
11. Resuspend in 22 µl nuclease free water from the SP6 kit listed below.

3.16 SP6 transcription

- The following reaction was setup using the SP6 transcriptase kit
- 20 (Epicentre) and Rnasin (Promega) in an RNase-free 1.5 ml tube using RNase-free tips in a BL-2 hood. The reaction was then placed in a 40°C water bath for 1 hour.

-79-

Total RNA control

5	PBS	250 μ l
	Lipofectin	20 μ l
	YF/JE total RNA	10 μ l
	Volume	280 μ l

Lipofectin control

10	PBS	260 μ l
	Lipofectin	20 μ l
	Volume	280 μ l

1. Allow reactions to sit at room temperature for 10 minutes, and then remove Media from the six well plates.
2. Wash 3 times with PBS.
- 15 3. Remove last of PBS.
4. Overlay with each lipofectin reaction (add the YF/DEN-1 RNA to the 2 x 10⁶ cells/well plate). Add 280 μ l media to the remaining wells.
5. Rock for 10 minutes at room temperature.
6. Wash 2 times with media.
- 20 7. Add 2 ml of media to each well and place in the 37°C CO₂ incubator for 4 days or more.

3.18 Harvest of the first Vero-PM passage (P1)

- The supernatant from YF/DEN-1 was harvested on day 6 by
- 25 splitting the 2 ml of supernatant between two cryovials (each containing 1

-81-

3. Five hundred ml of media (same as used for transfection) was added to the monolayer.
4. One ml of media only was added to a control flask.
5. The flasks were placed in a 37°C CO₂ incubator and rocked every 15 minutes for 1 hour.
6. Meanwhile, the remaining YF/DEN-1(P2) was harvested into 4 cryovials containing 1 ml FBS and 1 cryovial containing 0.5 ml FBS and labeled as YF/DEN-1(P2). The cell monolayer was harvested with 3 ml Trizol into 1.5 ml tubes. All vials were placed at -80°C in a box labeled YF/DEN-1.
7. After infection (Step 5), 4 ml of media was added to each flask and were transferred to the incubator for 4 or more days.

Harvest of P3

- The supernatant from YF/DEN-(P3) was harvested on day 5 by splitting the 5 ml of supernatant between five cryovials (each containing 1 ml FBS), which were labeled YF/DEN-1(P3). The cell monolayer was harvested with 3 ml Trizol into 1.5 ml tubes. All vials and tubes were then placed at -80°C.

3.20 Virus Identification

The RNA from P3 was extracted using Trizol methods according to the manufacturer's protocol, RT-PCR was performed followed by sequencing of the YF/DEN-1 prME region 5', 3' junctions, inclusive. The expected sequence of the prME region was confirmed.

-83-

strain of YF that includes the 5' and 3' UTRs, the C gene, and the nonstructural protein genes, NS1-5, (a prerequisite for safety).

To engineer a YF/DEN3 chimera containing the prM-E cassette from DEN3 in place of the prM-E cassette of YF we first wanted to use the two-plasmid approach that was successful in previous studies where 17D YF virus (Rice *et al.*, New Biol. 1:285-296, 1989) and the YF/JE chimera (Chambers *et al.*, J. Virol. 73:3095-3101, 1999) were recovered following *in vitro* transcription and transfection. The DEN3 (strain PaH881/88) prM-E region was RT-PCR amplified in two adjacent fragments (Fig. 29). To determine consensus sequence of this region of the parental virus, the RT-PCT fragments were directly sequenced in both directions. Since oligonucleotide primers used to synthesize these fragments were designed based on the published sequence of the H87 reference strain of DEN3 (Osatomi *et al.*, Virology 176:643-647, 1990), actual viral sequences in the primer areas (at the beginning of prM, nucleotides 437-459; at the junction between the two fragments, nucleotides 1079-1131; and at the end of E, nucleotides 2385-2413) could not be determined. A total of 83 nucleotides changes were found compared to H87 strain. The rate of nucleotides differences, 4.44%, was similar to that (4.5%) reported previously by Delenda *et al.* (J. Gen. Virol. 75:1569-1578, 1994) who sequenced roughly 80% of PaH881/88 E gene. Although the majority of nucleotides differences in the 80% E area coincided with those found by Delenda *et al.* (V. Deubel, personal communication) (53 changes coincided), there were 4 additional changes that were not found by Delenda *et al.* In addition, we did not observe 3 of the changes reported by these authors. The PaH881/88 virus (a starting material in our experiments) was isolated from a patient by single amplification in mosquito AP61 cells. We propagated this virus in C6/36,

-85-

by PCR (other sequenced clones contained more mutations). Therefore, the standard ChimeriVax procedure for preparation of infectious *in vitro* RNA transcripts that employs two fragment ligation prior to *in vitro* transcription was modified. According to the standard protocol, the large
5 BstBI-AatII fragment from 5.2/Den3 would be ligated with the large BstBI-AatII fragment of 5'3'/Den3/DXho (see in Fig. 30). Instead, to correct the deletion, three-fragment ligation was done (Fig. 30). The DEN-3 part of 5.2/Den3 was PCR-amplified on the #26 clone template with high-fidelity LA Taq polymerase and digested with BstBI and EheI
10 (isoschizomer of NarI). The opposite PCR primer was expected to correct the deletion. Second fragment, corresponding to the NarI-AatII part of 5.2/Den3, was derived by digestion of YFM5.2 JE SA14-14-2 with EheI and AatII. The two fragments were ligated with the large BstBI-AatII fragment of 5'3'/Den3/ Δ Xho. Ligation products were digested with XhoI
15 and transcribed *in vitro* with SP6 RNA polymerase.

Vero PM cells (at passage 149) grown in 6 well plates were transfected with the *in vitro* RNA transcripts. A first indication that the expected YF/DEN3 chimera was present was the appearance of CPE characteristic of other chimeras created to date based on the YF backbone.
20 It was first noticeable on day 5 post-transfection and became apparent (~10% of detached and rounded cells) on day 7 when virus-containing medium was harvested (P1). Subsequent P2 and P3 viruses were obtained by infecting fresh monolayers of Vero PM cells (at passages 150 and 151, respectively) with the P1 and P2 viruses (1 and 0.5 ml of the viruses were
25 used for each infection, respectively) and harvesting the virus when apparent CPE (~10%) was observable (on days 3 and 4 for P2, and day 3 for P3).

-87-

overcoming technical difficulties that are often encountered during cloning of genetic material from many flaviviruses in *E. coli* (especially dengue viruses). A viable 17D YF/DEN3 chimeric virus was recovered which is yet another successful example of the usefulness of the approach developed by Chambers *et al.* (Chambers *et al.*, J. Virol. 73:3095-3101, 1999; see above), in which the prM-E cassette of a heterologous flavivirus is inserted into the YF backbone such that the hydrophobic signal for prM remains YF-specific.

The materials and methods used to make and characterize the YF/DEN3 chimera are described as follows.

4.1 Virus and cells

DEN3 strain PaH881/88 was isolated from a patient by single amplification in AP61 (mosquito) cells. C6/36 cells were maintained in MEM (Gibco, Cat.# 11095-072) supplemented with 10% FBS (HyClone, Cat.# SH30070103) and 1x non-essential amino acids (Sigma, Cat.# M7145) (OraVax ML-8 medium, Lot.# 108H2308) at 28°C under 5% CO₂. DEN3 was passaged two times by infecting monolayers of C6/36 at an unknown MOI and harvesting virus-containing growth media on day 7 post-infection (P1 and P2) and one time by infecting C6/36 cells with the P2 virus at an MOI of ~ 0.01 pfu/cell and harvesting the medium on day 6 (P3; pronounced virus-specific CPE was observed in P3).

Virus-containing media were mixed with an equal volume of FBS, aliquoted and stored at 70°C. Following transfection/infection, Vero PM cells were maintained in MEM (Gibco, Cat.# 11095-080, Lot.# 1017611) supplemented with 5% heat-deactivated FBS (OraVax Lot.# AGE6578)

-89-

(ORAVAX/VOLTEMP/GROUPS/LABTECH/KOSTIA/folder "KP sequencing data"/Exp.##). With each area of interest, both DNA strands were sequenced and analyzed. Oligonucleotide primers are listed in Table 32.

- 5 Primers were ordered from Custom Primers (Life Technologies/GibcoBRL). In the names of primers, numbers indicate approximate localization of oligos on the DEN3 genome and "+/-" indicates orientation of each primer, with the following exceptions: oligo 5 is colinear with a region of YFM5'3' series of plasmids upstream from the
- 10 NotI cloning site; oligos 6 (opposite) and 7 (direct) are YF-specific; the former corresponds to the end of YF C gene; oligos 15 (direct) and 16 (opposite) were designed for amplification and sequencing of inserts in the YFM5.2 series of plasmids and correspond to regions of the plasmids located within ~ 60 nucleotides upstream and downstream from the
- 15 corresponding inserts, respectively; oligo 8 (direct) was used to mutate the XhoI site at nucleotide 1052 of the recombinant YF/DEN3 genome (within 5'3'/Den3 plasmid); and oligo 17 is colinear with the SP6 promoter and a few of the 5' terminal nucleotides from YF.

20 4.3 DNA manipulations

- Standard molecular biology techniques were in accordance with Maniatis *et al.*, Molecular Cloning: a Laboratory Manual, 2nd Edn. Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, 1992. All restriction enzymes, except for EheI (Fermentas) and T4 DNA ligase,
- 25 were from New England Biolabs.

-91-

the resulting 5'3'/Den3, which is a pBR322-based plasmid maintained in *E. coli* MC1061RecA- cells, was sequenced using oligos 1, 2, 9, 10, and 17, and a correct clone (#3) was selected, which does not have any mutations compared to the consensus sequence.

5 Sequencing revealed that the DEN3-specific portion of 5'3'/Den3 contains an additional XhoI site located in the beginning of E gene (nucleotides 1007-1012 in DEN3 genome). Another XhoI site used for linearization prior to *in vitro* transcription (see below) is located at the end of YF sequence in 5'3'/Den3. The additional site was destroyed by silent
10 oligonucleotide-directed mutagenesis (LA PCR; DEN3-specific C at nucleotide 1009 was changed to G) using oligo 8, resulting in a plasmid 5'3'/Den3/DXho. The entire region of the plasmid replaced during mutagenesis was sequenced with oligos 1, 2, 9, 10, and 17 and a clone (#10) was selected that does not have any mutations, except for the desired
15 C to G nucleotide change.

4.5 Construction of 5.2/Den3 plasmid

The 3' terminal part of DEN3 prM-E region was RT-PCR amplified (XL PCR) on the P3 virion RNA template using primers 3 and 4. It starts
20 with BstBI site introduced at nucleotides 1101-1106 for in-frame ligation with 5'3'/Den3/DXho plasmid and ends with a NarI site introduced precisely at the 3' end of E gene (nucleotides 2408-2413) for in-frame ligation with YF NS1. The NarI site that leads to Q to G change of the penultimate amino acid residue in the DEN3 E was used previously to
25 generate YF/JE chimera (Chambers *et al.*, J. Virol. 73:3095-3101, 1999; see above). An NheI cloning site was placed upstream from the BstBI site. The consensus sequence of this DEN3 region was determined by

-93-

AS2606C2). RNA transcripts were analyzed by electrophoresis of 2 μ l aliquots in 1% agarose gel. Monolayers of Vero PM cells grown in 6 well tissue culture plates were transfected with RNA transcripts using Lipofectin reagent (Gibco, Cat.# 18292-011). Following transfections, 5 cells were incubated as is described above, and virus-containing media were harvested on indicated days post-transfection, mixed with equal volume of FBS, aliquoted and stored at -70°C .

5.0 Construction of ChimeriVaxTM YF/DEN-4

10 The purpose was to generate yellow fever/dengue 4 (YF/DEN-4) chimeric virus as a dengue vaccine candidate (see Figs. 31 and 32). To attain this, we used a technology derived from the construction of Yellow fever/ Japanese encephalitis (YF/JE SA 14-14-2) chimeric virus (Chambers *et al.*, J. Virol. 73:3095-3101, 1999). It consists of a two 15 plasmid system which originally encoded the yellow fever (YF) genome. These YF plasmids were created by Charlie Rice (Rice *et al.*, New Biol. 1:285-296, 1989). The structural membrane precursor and envelope protein genes, *i.e.*, the prME portion, of the YF genome plasmids with that of JE SA14-14-2 sequence and used the resulting plasmids to produce 20 RNA *in vitro*, which was then transfected into cells to produce live YF/JE chimeric virus. The system seemed suitable to construct other flavivirus chimeras using YF as backbone and here we describe the use of dengue 4 as a start point. The dengue 4 strain, #1228 isolated in 1978 in Indonesia and passaged twice in Mosquitoes, was passed once in C6/36 and total 25 RNA was isolated to synthesize cDNA for PCR of the prME region as needed for cloning. Here we describe in detail the procedures for construction of the YF/DEN-4 chimera. The dengue 4 prME region was

-95-

- A) was amplified using the XL-PCR Reaction Kit TM (Perkin-Elmer Part# N808-0192), 0.5 ml (250 ng) of template pYF5'3'TV plus 3.5 ml RODI-water, and primers 1 and 2. The fragment encoding dengue 4 prM and the 5' end of E (Fragment B) was amplified using the XL-PCR Reaction Kit TM (Perkin-Elmer Part#N808-0192) and primers 3 and 4. The fragment encoding the 3' end of dengue 4 envelope (Fragment C) was amplified using the same protocol but using primers 5 and 6. Each PCR reaction was performed as indicated in master mixes (see section 3.1, above).
- 10 For each reaction, the lower mix (LM) was added to a Perkin-Elmer thin-walled 0.2 ml tube. Next, Ampliwax 100 (Perkin-Elmer) was added to the tube, which was then placed in a Perkin-Elmer 2400 Thermal Cycler and heated to 80°C for 5 minutes, and then cooled to 4°C. The cDNA and UM were then added to the top of the wax layer. The tube was then
- 15 cycled in a Perkin-Elmer 2400 as follows: 94°C, 1 minute; repeat 30 x (94°C, 15 seconds; 53°C, 15 seconds; 68°C, 3 minutes), 72°C, 4 minutes; 4°C, hold. The expected sizes of the PCR fragments for cloning were as follows:

Fragment	Approximate Size (kb)
A	0.940
B	0.650
C	1.300

- Forty µl of each fragment was then separated on a 1% Agarose/TAE gel and purified using the QIAquick Gel Extraction Kit (Qiagen cat#28704). Next, the concentration of the purified fragments was determined by UV absorption using 1:40 dilutions in RODI-water.

-97-

Forty μ l of Fragment E was then separated on a 1% Agarose/TAE gel and purified using the QIAquick Gel Extraction Kit (Qiagen cat#28704). Next, the concentration of the purified fragment was determined by UV absorption using 1:40 dilutions in RODI-water.

5	Sample	A280	A260	280/260	260/280	Concentration
	Fragment E	0.0049	0.0110	0.4489	2.2276	22 ng/ μ l

5.3 Cloning of Fragments C and E into Yellow Fever Vectors

The fragments were then cloned into the yellow fever two-plasmid system by digestion of the purified Fragments C and E as well as the plasmids pYF5'3'IV and pYFM5.2/2 with appropriate restriction enzymes as shown below. The digested plasmids resulted in two bands. The smaller bands contain a fragment of Japanese encephalitis corresponding to either Fragment C or Fragment E for the new dengue 4 constructs. All restriction enzymes, buffers, and 100x BSA were from New England Biolabs. All the digestions were carried in a Perkin-Elmer 480 cyclor set to hold at 37°C overnight.

Fragment E digest

20	Fragment E (528 ng)	27 μ l
	NEB buffer 4	4 μ l
	10x BSA	4 μ l
	H ₂ O	3 μ l
	Not I	1 μ l
	Nhe I	1 μ l
25	Volume	40 μ l

-99-

5.4 Vector Dephosphorylation

Calf Intestinal Phosphatase (CIP) from New England Biolabs (cat#290S) was diluted 1:10 in 1x CIP Buffer. One μ l of this dilution was then added to the pYFMIV5'3' digest. 0.62 μ l of stock CIP was added
5 directly to the pYF5.2 digest. Both were incubated for 1 hour at 37°C. Then, 0.8 μ l 125 mM EDTA was added to the two tubes and placed at 75°C for 10 minutes to inactivate CIP

5.5 Gel Excision

10 The digested PCR fragments were separated on a 1.0% Agarose/TAE gel, while the digested plasmids were separated on a 0.8% Agarose/TAE gel. All were purified using the QIAquick Gel Extraction Kit (Qiagen cat#28704).

15 5.6 Ligations

The digested Fragment E and pYF5'3'TV were ligated using T4 DNA Ligase (New England Biolabs cat#202S) to create pYD4-5'3'. The digested Fragment C and pYFM5.2 were ligated to create pYD4-5.2. All ligation reactions were incubated in a Perkin-Elmer 480 cyclor set to hold
20 at 16°C overnight.

-101-

pYF5.2 Control Ligation

	Fragment C	0 μ l
	pYFM5.2 (70 ng)	8.8 μ l
	H ₂ O	8.2 μ l
5	10x T4 ligase buffer	2 μ l
	T4 DNA ligase	1 μ l
	Volume	20 μ l

5.7 Transformations

10 All four ligation reactions were transformed into *E. coli* strain MC1061 (recA-). An aliquot of MC1061 (OraVax Notebook 661-4) was removed from storage at -80°C and allowed to thaw on ice for one to two minutes. 0.9 ml of cold 0.1 M CaCl₂ was added to the cells. One hundred μ l of cells was aliquoted into five 12 ml culture tubes on ice. Ten μ l of
15 each ligation reaction was added to each culture tube, leaving the fifth tube as a negative (no DNA) control. Culture tubes were left on ice for 30 minutes. The tubes were heat shocked in a water bath at 42°C for 45 seconds. The tubes were put back on ice for 2 minutes. 0.9 ml SOC medium was added to each culture tube and incubated at 225 pm in a
20 shaking incubator at 37°C for 1 hour. Each transformation mix was aliquoted into 1.5 ml microcentrifuge tubes. One hundred μ l of each was spread onto LB/Agar-Amp (100 μ g/ml) plates and labeled as "neat." Each tube was spun at 14 Krpm in a microcentrifuge for 2-3 seconds to pellet the cells. The supernatant was poured into the waste container and the
25 pellet resuspended in the residual broth by pipetting up and down. This material was plated (approximately 100 μ l) onto LB/Agar-Amp (100 μ g/ml) plates and labeled as 10x. All plates were inverted in a 37°C incubator overnight.

-103-

5.9 Glycerol Stocks

Five ml of LB-Amp (100 µg/ml) was then inoculated from a patch pYD4-5'3'/2 or pYD4-5.2/1 and shaken at 225 rpm overnight at 37°C.

One ml of this culture was then spun at 14 Krpm for 2-3 seconds to pellet the cells. This was then resuspended in LB-Glycerol (30%) and frozen at -80°C.

5.10 MIDI Plasmid Preparation

Fifty µl of each glycerol stock was added to 150 ml LB-Amp (100 µg/ml) in separate 4 L flasks and shaken at 225 rpm overnight at 37°C. Qiagen Midi-Prep (Qiagen) was performed using the following modified protocol.

1. Spin 150 ml of each culture at 7 Krpm in GSA rotor for 10 minutes to pellet.
2. Decant Supernatant.
3. Resuspend pellet in 4 ml P1 Buffer; transfer to 50 ml Falcon tube.
4. Rinse centrifuge bottle with 2 ml P1 buffer and transfer to the Falcon tube.
5. Add 6 ml P2 buffer; invert gently; 5 minutes at room temperature or until lysed (no more than 12 minutes).
6. Add 6 ml P3; mix as above; 10 minutes on ice.
7. Transfer supernatant to Qiagen Syringe Filter; let sit for 10 minutes.
8. Equilibrate Q-100 tip with 4 ml QBT.
9. Gently push plunger to filter supernatant onto Q-100 tip.
10. Allow to drain by gravity.

-105-

YD4-5.2/1 (AatII digest)

5	pYD4-5.2 (10 µg)	35.5 µl
	Buffer 4 (NEB)	5 µl
	AatII (NEB)	2 µl
	H ₂ O	7.5 µl
	Volume	50 µl

Both reactions were incubated in a 37°C block for 2 hours. Five µl of each digest was run out on a 1.5% Agarose/TAE gel to check for complete digestion. The pYD4-5'3'/2 digest did not cut completely so the reaction was cleaned over a Qiaprep spin column (Qiagen). The digest was repeated using this material and 3 µl of Aat II. In addition, 3 µl of Aat II was added to the existing pYD4-5.2/1 reaction. Both were incubated in a 37°C block, overnight. After confirmation of digest on another gel (as previously described), 2.5 µl Bst BI (NEB) was added to each reaction and placed at 65°C for 3 hours. The results of the digest were as follows.

20	PYD4-5'3'/2	PYD4-5.2/1
	5.6 kb	7.2 kb
		2.0 kb
	0.14 kb	0.4 kb

The largest band from each reaction was gel excised as and the UV concentration was determined (as previously described).

25 5.12 Ligation

The following ligation reaction was setup using high concentration T4 DNA ligase (NEB). The ligations were incubated at 16°C overnight.

-107-

6. Place on dry-ice/ethanol bath for 10 minutes.
7. Spin at 14 Krpm for 20 minutes in a microcentrifuge.
8. Wash with 200 μ l 70% ethanol (RNase-free).
9. Repeat 70% ethanol wash two more times.
- 5 10. Dry in Speed-Vac for 8 minutes (or until no more ethanol is present).
11. Resuspend in 22 μ l nuclease free water from the SP6 kit listed below.

5.15 SP6 transcription

The following reaction was setup using the SP6 transcriptase kit (Epicentre) and Rnasin (Promega) in an RNase-free 1.5 ml tube using RNase-free tips in a BL-2 hood. The reaction was then placed in a 40°C water bath for 1 hour.

	Capping NTP solution	6 μ l
	10x buffer	2 μ l
15	20 mM Cap Analog	3 μ l
	100 mM DTT	2 μ l
	Linearized DNA	5 μ l
	Rnasin	0.5 μ l
	SP6 transcriptase	2 μ l
20	Volume	20.5 μ l

5.16 RNA Transfection

Two six well tissue culture plates were seeded with Vero-PM (p#153 OraVax notebook#743-7) cells at 7.4×10^5 cells/well in growth

-109-

5. Rock for 10 minutes at room temperature.
6. Wash 2 times with media (MEM, Sodium Pyruvate, NEAA, P/S, 5% FBS).
7. Add 2 ml of media to each well and place in the 37°C CO₂ incubator for 4 days or more.

5.17 Chimeric Virus Harvest

The supernatant from YF/DEN-4 was harvested on day 6 by splitting the 2 ml of supernatant between two cryovials (each containing 1 ml FBS), which were labeled YF/DEN-4 (P1). The cell monolayer was harvested with 1 ml Trizol into a 1.5 ml tube. All vials and tubes were then placed at -80°C.

5.18 Amplification of YF/DEN-4

15 Passage #2

1. Three T-25 flasks containing Vero-PM cells (p#149) were obtained from the Cell Culture Facility. A frozen aliquot of YF/DEN-4 (P1) was removed from the -80°C freezer, thawed, then placed on ice. The same was done for an aliquot of YF/JE (frozen stock from the P1 control transfection).
2. Media was removed from each T-25 flask.
3. Five hundred µl of YF/DEN-4(P1) was added to the first flask, 500 µl of media (MEalphaM, NEAA, Sodium Pyruvate, 5% FBS, P/S) was added to the second flask, and 500 µl of YF/JE(P1) was added to the third flask.

25

-111-

23 ml Agarose (0.6% in water) was heated at 42°C in a 50 ml Falcon tube (tube #2). At the end of the 1 hour incubation, tube #1 was added to tube #2 and mixed thoroughly.

6. One ml of this overlay was then added to the edge of each well.

5 7. The plate was then put in the 37°C CO₂ incubator for 4 days.

8. The 2° overlay was made by preheating 25 ml M199(2X), 1.5 ml FBS, 1.5 ml Neutral Red, and 0.5 ml PSA at 42°C in a 50 ml Falcon tube (tube #1). Additionally, 21.5 ml Agarose (0.6% in water) was heated at 42°C in a 50 ml Falcon tube (tube #2). Tube #1 was added to tube #2 and mixed
10 thoroughly.

9. One ml of this overlay was added to the center of each well.

10. It was then placed in the 37°C CO₂ incubator

Titration of P2 results

Instead of titer determination, plaques were picked for purification
15 to segregate a mixed population of large and small plaques observed. The RNA from P2 was extracted using Trizol methods according to the manufacturer's protocol, RT-PCR was performed followed by sequencing of the YF/DEN-4 prME region 5', 3' junctions, inclusive. The expected sequence of the prME was confirmed.

20

6.0 Construction of Chimeric Templates for Other Flaviviruses

Procedures for generating full-length cDNA templates encoding chimeric YF/MVE, YF/SLE, YF/WN, YF/TBE viruses are similar to those described above for the YF/DEN-2 system. Table 20 illustrates the
25 features of the strategy for generating YF 17D-based chimeric viruses. The unique restriction sites used for *in vitro* ligation, and the chimeric

-113-

exceeding the normal size of the genome (approximately 10,000 nucleotides), the detection strategy described below can be used. In addition, deletion of NS1 may be advantageous in the chimeric YF/Flavivirus systems described above, because partial deletion of this

5 protein may abrogate the immunity to YF associated with antibodies against NS1, and thus avoid problems with vector immunity if more than one chimeric vaccine was to be needed in a given recipient, or if a YF vaccine had been previously given or needed at a future point.

The strategy involves creating a series of in-frame deletions within

10 the NS1 coding region of the YFM5.2 plasmid, in conjunction with engineering a translational termination codon at the end of E, and a series of two IRESs (internal ribosome entry sites). One IRES is immediately downstream of the termination codon and allows for expression of an open reading frame within the region between E and NS1. The second IRES

15 initiates translation from truncated NS1 proteins, providing expression of the remainder of the YF nonstructural polyprotein. These derivatives are tested for recovery of infectious virus and the construct with the largest deletion is used for insertion of foreign sequences (*e.g.*, HCV proteins) in the first IRES. This particular construct can also serve as a basis for

20 determining whether deletion of NS1 will affect vector-specific immunity in the context of YF/Flavivirus chimeric viruses expressing prM-E, as described above.

The insertion of nucleotides encoding E1, E2, and/or E1 plus E2 HCV proteins is limited by the size of the deletion tolerated in the NS1

25 protein. Because of this, truncated HCV proteins can be used to enhance stability within the modified YF clone. The HCV proteins are engineered with an N-terminal signal sequence immediately following the IRES and a

-115-

deposit date of January 6, 1998: Chimeric Yellow Fever 17D/Dengue Type 2 Virus (YF/DEN-2; ATCC accession number ATCC VR-2593) and Chimeric Yellow Fever 17D/Japanese Encephalitis SA14-14-2 Virus (YF/JE A1.3; ATCC accession number ATCC VR-2594).

1,2: The column illustrates the oligonucleotide used to generate chimeric YF/Flavivirus primers corresponding to the C/prM or E/NS1 junction. (See text). X = carboxyl terminal coding sequence of the YF capsid. The underlined region corresponds to the targeted heterologous sequence immediately upstream of the *NarI* site (antisense - ccgagg). This site allows insertion of PCR products into the Yfm5.2 (*NarI*) plasmid required for generating full-length cDNA templates. Other nucleotides are specific to the heterologous virus. Oligonucleotide primers are listed 5' to 3'.

3,4: The unique restriction sites used for creating restriction fragments that can be isolated and ligated *in vitro* to produce full-length chimeric cDNA templates are listed. Because some sequences do not contain convenient sites, engineering of appropriate sites is required in some cases (footnote 5).

5: In parentheses are the restriction enzyme sites that must be created either in the YF backbone or the heterologous virus to allow efficient *in vitro* ligation. Sites not in parentheses must be eliminated. All such modifications are done by silent mutagenesis of the cDNA for the respective clone. Blank spaces indicate that no modification of the cDNA clones is required.

Table 26. Immunogenicity of ChimeriVax™-D2 passed in Vero cells for mice

Passage level ^a	Dose (Log ₁₀ pfu)	GMT ^b	
		SC	IC
P3	5	1 ± 0 ^c	61 ± 47
	4	1 ± 0	7 ± 15
P5	5	1 ± 0	46 ± 16
	4	1 ± 0	9 ± 20
P10	5	1.8 ± 7.7	46 ± 53
	4	1 ± 0	7 ± 15
P18	5	1 ± 0	53 ± 17
	4	1 ± 0	2 ± 16

a: ChimeriVax™-Den2 virus was passaged in Vero _{PM} cells (P141-147) at MOI of 0.1-0.5 and harvested 2-3 days PI.

B: Geometric Mean Titers measured as the last dilution of sera which resulted in 50% reduction in number of virus plaques.

C: Titers less than 1:10

Table 27. Immunization and challenge of yellow fever immune monkeys

-143-

(Gresikova *et al.*, "Tick-borne Encephalitis," In *The Arboviruses, Ecology and Epidemiology*, Monath (ed.), CRC Press, Boca Raton, Florida, 1988, Volume IV, 177-203), the vaccine virus can be administered by a mucosal route to achieve a protective immune response. The vaccine can be
5 administered as a primary prophylactic agent in adults or children at risk of flavivirus infection. The vaccines can also be used as secondary agents for treating flavivirus-infected patients by stimulating an immune response against the flavivirus.

It may be desirable to use the yellow fever vaccine vector system
10 for immunizing a host against one virus (for example, Japanese Encephalitis virus) and to later reimmunize the same individual against a second or third virus using a different chimeric construct. A significant advantage of the chimeric yellow fever system is that the vector will not elicit strong immunity to itself. Nor will prior immunity to yellow fever
15 virus preclude the use of the chimeric vaccine as a vector for heterologous gene expression. These advantages are due to the removal of the portion of the yellow fever vaccine E gene that encodes neutralizing (protective) antigens to yellow fever, and replacement with another, heterologous gene that does not provide cross-protection against yellow fever. Although YF
20 17D virus nonstructural proteins may play a role in protection, for example, by eliciting antibodies against NS1, which is involved in complement-dependent antibody mediated lysis of infected cells (Schlesinger *et al.*, J. Immunology 135:2805-2809, 1985), or by inducing cytotoxic T cell responses to NS3 or other proteins of the virus, it is
25 unlikely that these responses will abrogate the ability of a live virus vaccine to stimulate neutralizing antibodies. This is supported by the facts that (1) individuals who have been previously infected with JE virus respond to vaccination with YF 17D similarly to persons without previous

-145-

therapy methods to introduce therapeutic gene products into a patient's cells and in cancer therapy. In these methods, genes encoding therapeutic gene products are inserted into the vectors, for example, in place of the gene encoding the prM-E protein.

- 5 Yellow fever 17D virus targets cells of the lymphoid and reticuloendothelial systems, including precursors in bone marrow, monocytes, macrophages, T cells, and B cells (Monath, "Pathobiology of the Flaviviruses," pp. 375-425, in Schlesinger & Schlesinger (Eds.), *The Togaviridae and Flaviviridae*, Plenum Press, New York 1986). The
- 10 yellow fever 17D virus thus naturally targets cells involved in antigen presentation and immune stimulation. Replication of the virus in these cells, with high-level expression of heterologous genes, makes yellow fever 17D vaccine virus an ideal vector for gene therapy or
- immunotherapy against cancers of the lymphoreticular system and
- 15 leukemias, for example. Additional advantages are that (1) the flavivirus genome does not integrate into host cell DNA, (2) yellow fever virus appears to persist in the host for prolonged periods, and (3) that heterologous genes can be inserted at the 3' end of the yellow fever vector, as described above in the strategy for producing a Hepatitis C vaccine.
- 20 Yellow fever 17D virus can be used as a vector carrying tumor antigens for induction of immune responses for cancer immunotherapy. As a second application, yellow fever 17D can be used to target
- lymphoreticular tumors and express heterologous genes that have anti-tumor effects, including cytokines, such as TNF-alpha. As a third
- 25 application, yellow fever 17D can be used to target heterologous genes to bone marrow to direct expression of bioactive molecules required to treat hematologic diseases, such as, for example, neutropenia; an example of a bioactive molecule that can be used in such an application is GM-CSF, but

-147-

1. A chimeric live, infectious, attenuated virus, comprising:
a yellow fever virus in which the nucleotide sequence encoding a prM-E protein is either deleted, truncated, or mutated so that functional yellow fever virus prM-E protein is not expressed, and
5 integrated into the genome of said yellow fever virus, a nucleotide sequence encoding a prM-E protein of a second, different flavivirus, so that said prM-E protein of said second flavivirus is expressed.
2. The chimeric virus of claim 1, wherein said second flavivirus is selected from the group consisting of a Japanese Encephalitis (JE) virus, a
10 Dengue virus selected from the group consisting of Dengue types 1, 2, 3, and 4, a Murray Valley Encephalitis virus, a St. Louis Encephalitis virus, a West Nile virus, a Tick-borne Encephalitis virus (*i.e.*, a Central European Encephalitis virus or a Russian Spring-Summer Encephalitis virus), a Hepatitis C virus, a Kunjin virus, a Powassan virus, a Kyasanur Forest
15 Disease virus, and an Omsk Hemorrhagic Fever virus.
3. The chimeric virus of claim 1, wherein said second flavivirus is a Dengue virus, and nucleotide sequences derived from said Dengue virus are derived from two or more different Dengue strains.

-149-

8. The use of claim 7, wherein said second flavivirus is selected from the group consisting of a Japanese Encephalitis (JE) virus, a Dengue virus selected from the group consisting of Dengue types 1, 2, 3, and 4, a Murray Valley Encephalitis virus, a St. Louis Encephalitis virus, a West Nile virus, a Tick-borne Encephalitis virus (*i.e.*, a Central European Encephalitis virus or a Russian Spring-Summer Encephalitis virus), a Hepatitis C virus, a Kunjin virus, a Powassan virus, a Kyasanur Forest Disease virus, and an Omsk Hemorrhagic Fever virus.

9. The use of claim 7, wherein second flavivirus is a Dengue virus, and nucleotide sequences derived from said Dengue virus are derived from two or more different Dengue strains.

10. The use of claim 7, wherein the nucleotide sequence encoding the prM-E protein of said second, different flavivirus replaces the nucleotide sequence encoding the prM-E protein of said yellow fever virus or comprises a mutation that prevents prM cleavage to produce M protein.

11. The use of claim 7, wherein the prM signal of said chimeric virus is that of yellow fever virus.

-151-

15. The nucleic acid molecule of claim 13, wherein second flavivirus is a Dengue virus, and nucleotide sequences derived from said Dengue virus are derived from two or more different Dengue strains.

16. The nucleic acid molecule of claim 13, wherein the nucleotide
5 sequence encoding the prM-E protein of said second, different flavivirus replaces the nucleotide sequence encoding the prM-E protein of said yellow fever virus or comprises a mutation that prevents prM cleavage to produce M protein.

17. The nucleic acid molecule of claim 13, wherein the prM signal
10 of said chimeric virus is that of yellow fever virus.

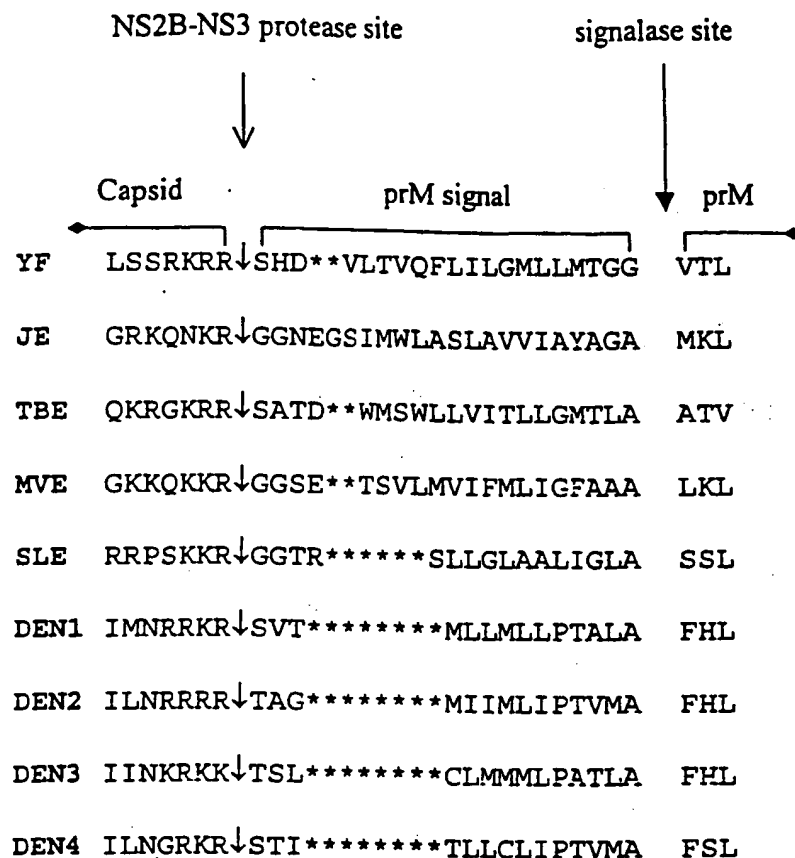

18. The nucleic acid molecule of claim 13, wherein NS2B-NS3 protease recognition site and the signal sequences and cleavage sites at the C/prM and E/NS1 junctions are maintained in construction of said chimeric flavivirus.

15 19. Use of a yellow fever virus vector comprising a gene encoding a gene product in the preparation of a medicament for producing said gene product in a cell of a patient.

20. The use of claim 19, wherein said cell is a cell of the lymphoid system or the reticuloendothelial system, or a precursor thereof.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US00/32821

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-6

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US00/32821

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be searched, the appropriate additional search fees must be paid.

Group I, claim(s) 1-6, drawn to a chimeric live, infectious, attenuated virus.

Group II, claim(s) 7-12, drawn to a method of using a chimeric, live, infectious, attenuated virus.

Group III, claim(s) 13-18, drawn to a nucleic acid molecule encoding a chimeric live, infectious, attenuated virus.

Group IV, claim(s) 19-22, drawn to a method of using a yellow fever virus vector.

and it considers that the International Application does not comply with the requirements of unity of invention (Rules 13.1, 13.2 and 13.3) for the reasons indicated below:

The inventions listed as Groups I-IV do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: The invention of group I does not make a contribution over the prior art as evidence by Chambers et al. (WO 98/37911). Since the chimeric, live, infectious, attenuated yellow fever virus is taught in the art as evidence by Chambers et al. (WO 98/37911) the invention lacks unity on the invention as defined by PCT Rule 13.2. The cited reference proves that the technical feature of the Group I does not make a contribution over the prior art, accordingly, the unity of the invention is lacking among all groups.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☐ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☐ **GRAY SCALE DOCUMENTS**
- ☐ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☐ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
